

We are going to show from beginning to end how to wire up a generic 8-bit machine. This machine will use a 2-operand format, meaning that instructions are of the time $A=A+B$. So, for example, "Add r0, r1" is $r0=r0+r1$.

The machine is byte-addressable. Offsets are sign-extended, and jumps are done by adding the sign-extended offset field to the PC. Immediates are not sign-extended.

The machine has 3 different instruction formats: A, B, and C.

A-type:	Opcode 7-4	ds 3	s 2	extra 1-0
---------	---------------	---------	--------	--------------

B-type:	Opcode 7-4	ds 3	Immediate 2-0
---------	---------------	---------	------------------

C-type:	Opcode 7-4	Offset 3-0
---------	---------------	---------------

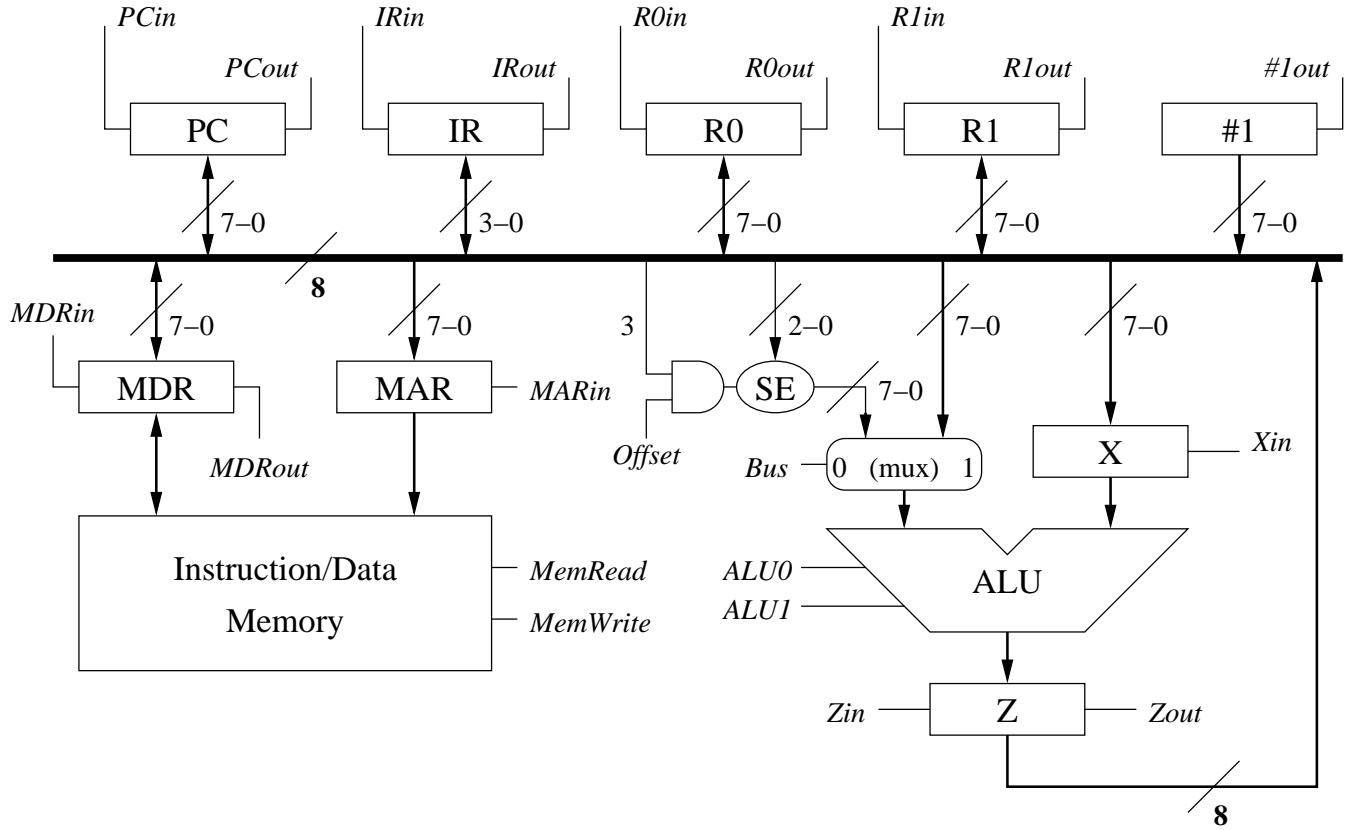

The ALU can perform 4 functions:

Operation	ALU0	ALU1
Add	1	1
Or	1	0
And	0	1
Not A	0	0

Here are a few of the instructions that have been defined:

Name	Opcode	Operation
add	0001	$rds=rds+rs$
addm	0010	$rds=rds+mem[rs]$
addi	0011	$rds=rds+imm$
jmp	1111	PC=PC+offset (offset is sign extended)

On the following page is a diagram of the machine. The control signals are in italics. MAR does not need an "out" signal, because the MemRead and MemWrite signals control whether or not memory looks at the MAR signal. The X register does not need an "out" signal either - the ALU will always perform an operation, which we can ignore if we want. The "#1" register contains the number 1, which is used to increment the PC. The SE block is sign-extend logic, and needs some further explanation. The problem is that the ALU requires an 8-bit value, but the Immediate field is only 3 bits wide, and the offset field is only 4 bits wide and also needs to be sign-extended. The sign extend logic creates a 5-bit value which matches the contents of bit 3, so that the 8-bit value generated looks like 33333210 (instead of 76543210). The AND gate is necessary because an immediate instruction is not sign-extended, and there needs to be a way to ensure that the top 5 bits are all set to zero.

Here are the 21 control signals.

PCin	PCout	IRin	IRout	R01	R0out	#1out
R1in	R1out	MDRin	MDRout	Zin	Zout	MARin
Xin	ALU0	ALU1	MemRead	MemWrite	Bus	Offset

In order to execute an instruction, we must make sure that each of these control signals is set to the appropriate value at the appropriate time. For example, here are the steps necessary to fetch an instruction from memory:

S t e p	P C i n	P C o u t	I R i n	I R o u t	R 0 i n	R 0 o u t	R 1 i n	R 1 o u t	M D i n	M D r o u t	Z i n	Z o u t	M A r i n	X i n	# 1 o u t	A L i n	A L u t	M r e a d	M w r i t e	B u s	O f f s e t
0	0	1	0	0	0	0	0	0	0	0	0	0	0	1	1	0	0	0	1	0	0
1	0	0	0	0	0	0	0	0	0	0	0	1	0	0	0	1	1	1	1	0	1
2	1	0	0	0	0	0	0	0	0	0	0	0	1	0	0	0	0	0	1	0	0
3	0	0	1	0	0	0	0	0	0	1	0	0	0	0	0	0	0	0	0	0	0

Once the instruction has been fetched, it must be executed. Here is how $R0 = R0 + R1$ would be performed:

S t e p	P C i o n	P C r i o n	I R 0 i o n	I R 0 i o n	R 0 i o u t	R 1 o u t	M D R i n	M D R o u t	Z i n	Z o u t	M A R i n	X i n	# 1 o u t	A L U 0	A L U 1	M r e a d	M w r i t e	M w r i t e	B u s	O f f s e t
0	0	0	0	0	0	1	0	0	0	0	0	1	0	0	0	0	0	0	0	0
1	0	0	0	0	0	0	0	1	0	0	1	0	0	0	0	1	1	0	0	1
2	0	0	0	0	1	0	0	0	0	0	1	0	0	0	0	0	0	0	0	0

Here is how a Jump would be performed (0's are removed for legibility reasons):

S t e p	P C i o n	P C r i o n	I R 0 i o n	I R 0 i o n	R 0 i o u t	R 1 o u t	M D R i n	M D R o u t	Z i n	Z o u t	M A R i n	X i n	# 1 o u t	A L U 0	A L U 1	M r e a d	M w r i t e	M w r i t e	B u s	O f f s e t
0		1											1							
1			1							1						1	1			1
2	1										1									

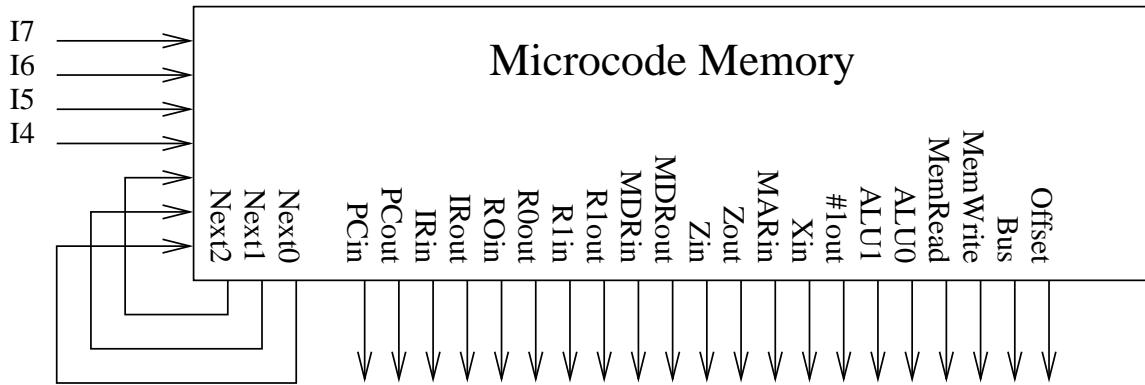

Here is an Immediate ($R0 = R0 + immd$) instruction:

S t e p	P C i o n	P C r i o n	I R 0 i o n	I R 0 i o n	R 0 i o u t	R 1 o u t	M D R i n	M D R o u t	Z i n	Z o u t	M A R i n	X i n	# 1 o u t	A L U 0	A L U 1	M r e a d	M w r i t e	M w r i t e	B u s	O f f s e t
0				1									1							
1			1							1						1	1			
2				1							1									

A memory access ($R1 = R1 + \text{mem}[R0]$):

S t e p	P C i o n	P C r i o n	I R 0 i o n	I R 0 i o n	R 0 i o u t	R 1 o u t	M D R i n	M D R o u t	Z i n	Z o u t	M A R i n	X i n	# 1 o u t	A L U 0	A L U 1	M r e a d	M w r i t e	M w r i t e	B u s	O f f s e t
0					1								1					1		
1						1							1					1		
2									1	1						1	1			1
3							1				1									

Once every instruction has been fully specified in this manner, one can go back and create sequential logic circuits which will cause each control signal to be set to the right value at the right time. However, if there are any changes or to the design (additions or modifications), then it will take substantial effort to generate an entire new set of sequential logic circuits. It is much easier to create a small memory which will contain the values of the control signals during each cycle, and then all we have to do is cycle through the memory correctly. For example, suppose I create a memory which is 24 bits wide, and addressed by using the top 4 bits of the opcode and the left most 3 bits of the memory output. It would look like this:

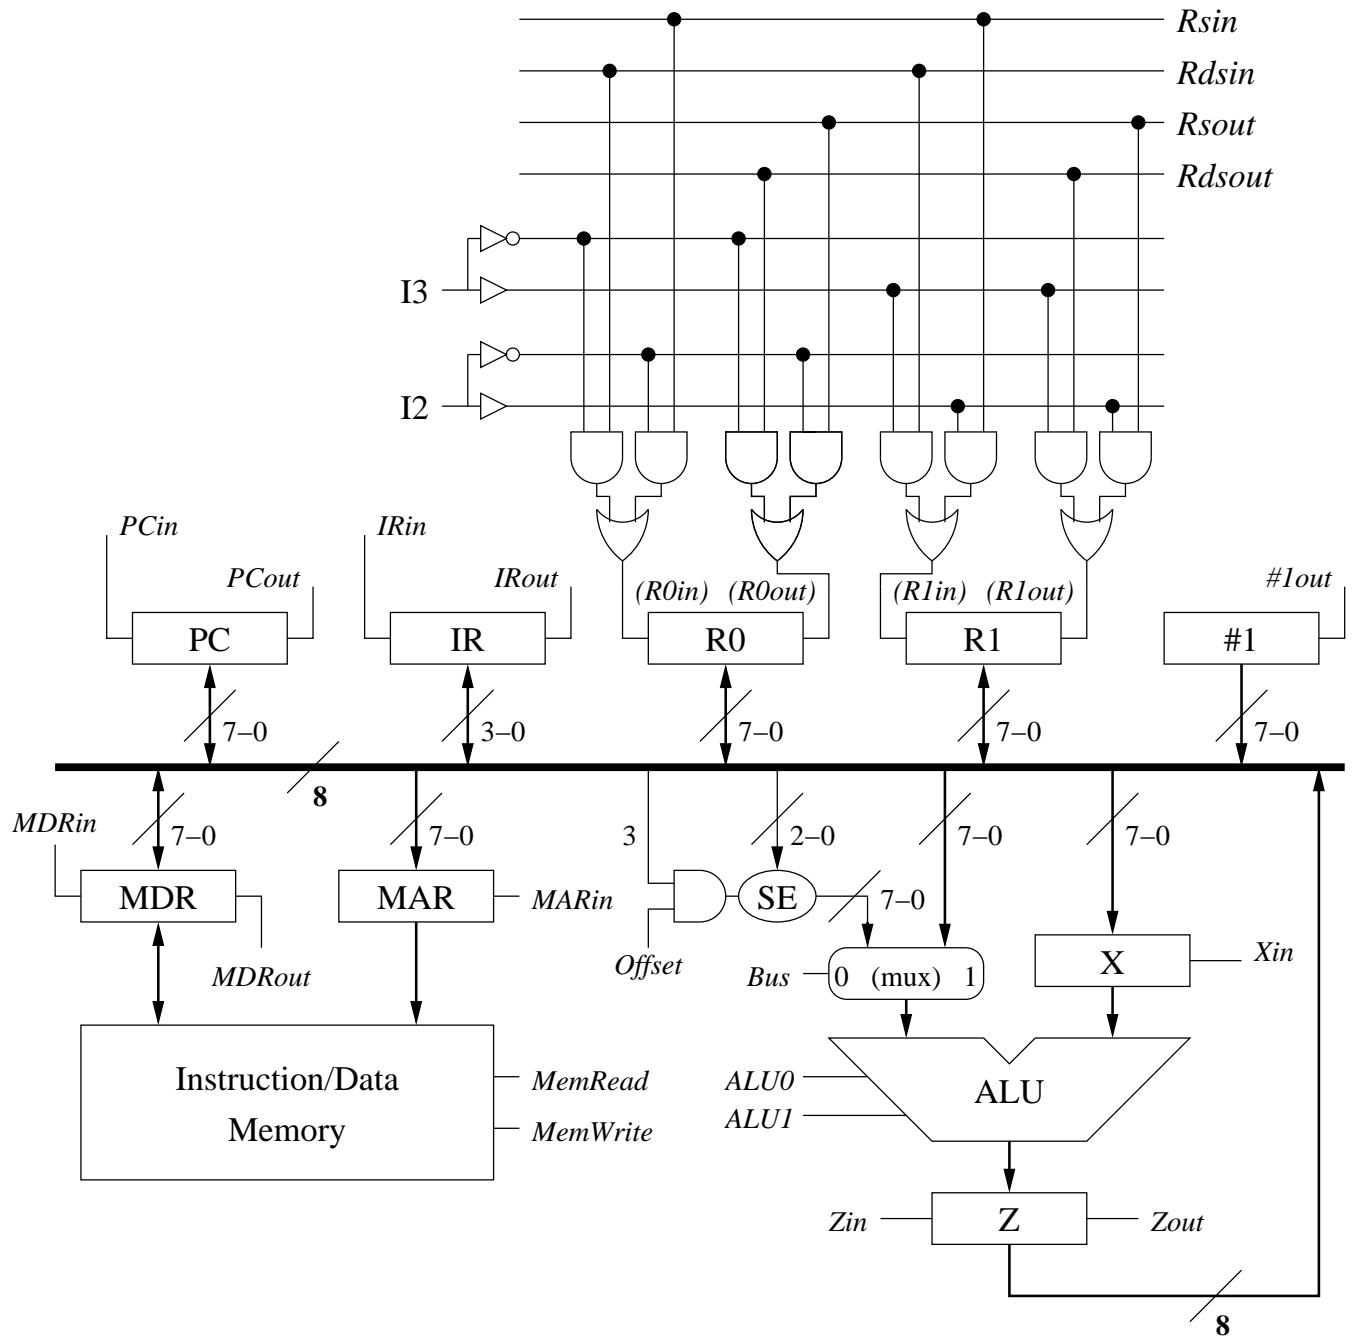

Using this approach, the control memory would look something like the table on the following page. What happens is the following: The top 4 bits of the IR provide the location in the memory where the steps to execute that instruction reside. The Next bits step us through the sequence of operations. Once the sequence has completed, we return to the xxxx000 location and perform the instruction fetch. After the 4th step of the instruction fetch, the IR will be loaded with a new instruction, and we will then go to that part of the control memory and perform the appropriate steps.

Thus, in this case, the magic "decode" stage amounts to nothing more than jumping to the correct part of the memory! The table on the following page shows some of the contents of the microcode memory.

Control Memory Address	N e x t 2	N e x t 1	N e x t 0	P C o u t	P C o u t	I R o u t	I R o u t	R 0 o u t	R 1 i n	R 1 o u t	M D R o u t	M D R o u t	Z i n	Z o u t	M A R i n	X i n	# 1 o u t	A L U 0	A L U 1	M r e a d	M w r i t e	B u s	O f f s e t

As I discussed in class, the actual diagram needs to be modified a bit in order to incorporate the fact that the instruction specifies which register is to be the source and which is to be the destination. The modified diagram would look like this:

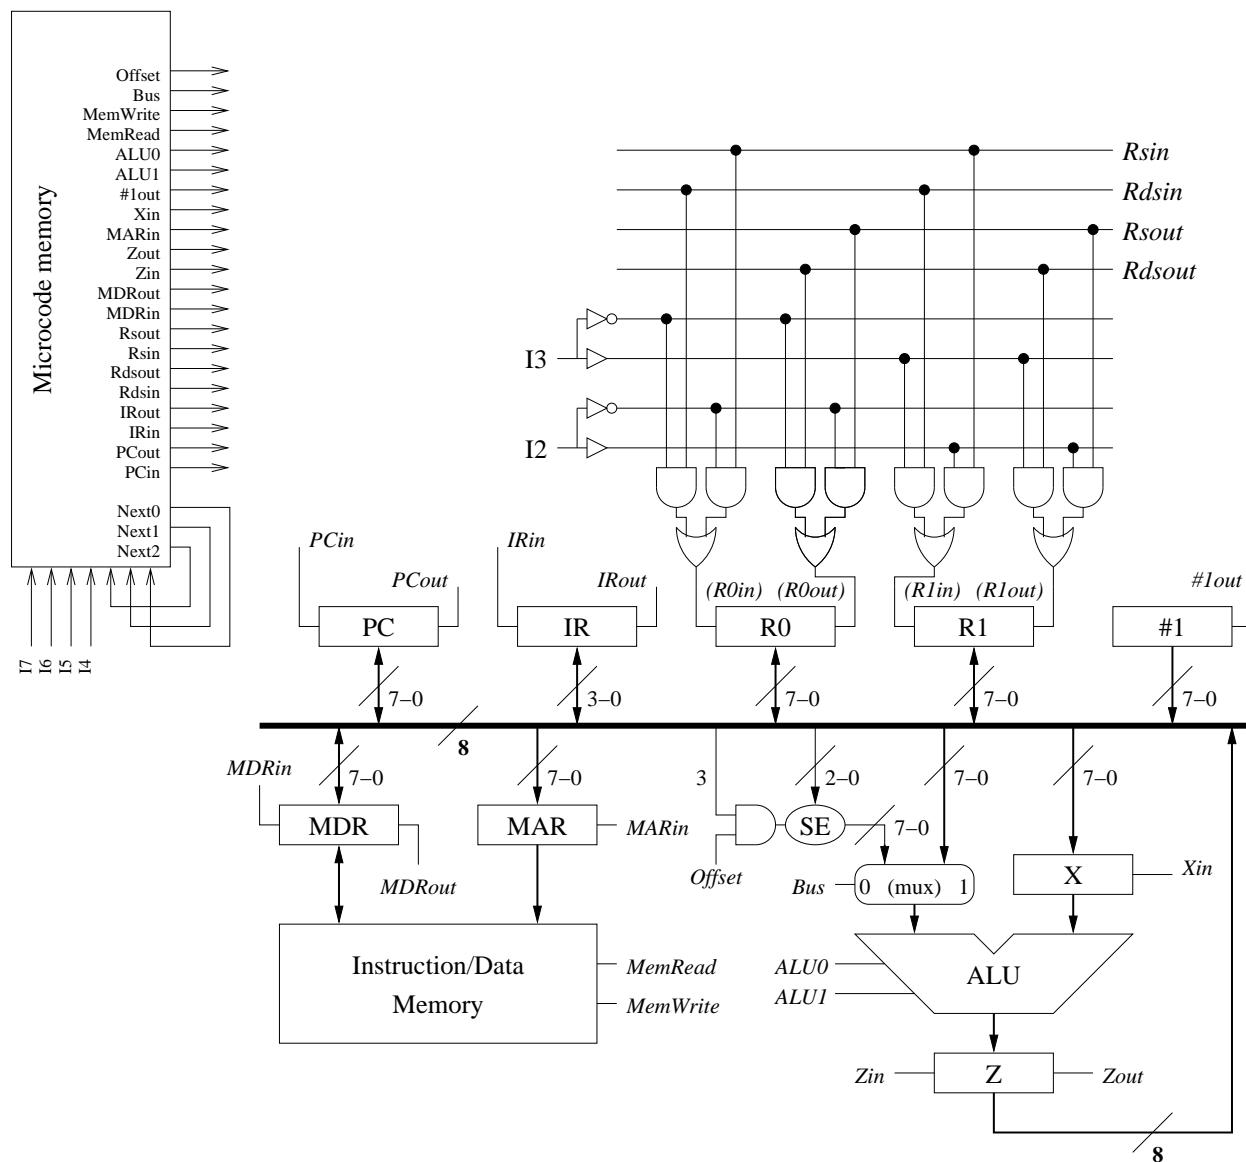

This would not require any new signals, we would just need to rename 4 of them. $R0in$, $R0out$, $R1in$, and $R1out$ would become $Rdsin$, $Rdsout$, $Rsin$, and $Rsout$.

The microcode steps in order to perform an add would look like this:

S t e p	P C o u t	P C o u t	I R o u t	I R o u t	R d s o u t	R d s o u t	R s o u t	M D R i n	M D R i n	Z i n	Z o u t	M A R i n	X i n	# 1 o u t	A L U 0	A L U 1	M r e a d	M w r i t e	M B u s	O f f s e t	
0															1						
1											1			1				1	1		1
2					1									1							

The machine, including the microcode, would look like this:

Suppose the IR currently contains 0 0 0 1 1 0 0 0, and will contain 1 1 1 1 0 1 1 0 next. Let's see if we can walk through what is happening in the microcode. Here is step 0 of fetch:

Control Memory Address	N e x t 2	N e x t 1	N e x t 0	P C o u t	P C o u t	I R o u t	I R o u t	R 0 o u t	R 1 i n	R 1 o u t	M D R i n	M D R o u t	Z i n	Z o u t	M A R i n	X i n	# 1 o u t	A L U 0	A L U 1	M r e a d	M w r i t e	B u s	O f f s e t

At this point, we have finished the jump instruction, and we will now begin fetching the next instruction. This is the final step of the fetch. After this cycle, the IR will contain a new value, and we will go to the appropriate entry in the table based on the top 4 bits in the IR, and repeat the entire process. Forever. Or at least until it crashes. :-)
